DAY6: Strings Operations

1.Indexing

→ Indexing is used to get char that you looking to access

types

1.positive indexing: positive indexing starts from 0 index

syntax→ print(variable_name[index_position])

Eg:

text ='python'

print(text[3])

2.negative indexing: negative indexing starts from -1 index

syntax→ print(variable_name[negative index_position])

Eg:

text ='python'

print(text[-1])

2.len ( )

→ len () is built-in function that is used to get number of the char present in the string

syntax→ len(varable_name)

Eg:

txt ='python is a programming language'
print(len(txt))

3.sciling

→ This is used to access the particular part from the string

syntax→variable_name[start:end]

Eg:

```
txt ='python is a programming language'
print(txt[0:6])
```

```
txt ='python is a programming language'
print(txt[12:])
```

```
txt ='python is a programming language'
print(txt[:23])
```

4.upper ()

→ used to convert all small char into cap

Eg:

```
txt ='python is a programming language'
print(txt.upper())
```

5.lower()

→ used to convert all cap char into small

Eg:

```
txt ='PYTHON IS A PROGRAMMING LANGUAGE'
print(txt.lower())
```

6.index()

→ used to know the index position of an char

syntax→variable_name.index('substring',start,end))

Eg:

```
txt ='python is a programming language'
print(txt.index('g'))
print(txt[15])
```

7.replace

→ used to replace old substring with new substring

syntax→ variable_name.replace(old,new)

Eg:

```
txt ='python is a programming language'
print(txt.replace('python','java'))
```

8.Split

→ This is method is used to separate the string based on the given substring

syntax→ variable_name.split(substring)

Eg:

```
txt ='Python is a programming language'
print(txt.split())
```

9.count

→ Used to count number of occurreneces of an substring

syntax→ variable_name.count('substring')

Eg:

```
txt ='Python is a programming language'
print(txt.count('g'))
```

10.Concatenate

—used to combine two string into one single string

syntax→ variable_1 + variable_2

Eg:

```
str_1='victor'
str_2='von'
str_3='doom'
print(str_1+str_2+str_3)
```
