

DAY2: Diving Deeper into Python — Understanding Tokens, Identifiers, & Syntax Rules!

What are tokens?

→ Tokens are the small unit in the python...

what are Identifier?

→ Identifier is a of variable or function or class

1.variable→

```
num = 'python'  
print(type(num))
```

2.functions

```
def add_(a,b);  
    print(a+b)  
add_(4,5)
```

3.class

class details:

```
    pass
```

```
per_1 =details
```

4.Keywords

→ Keywords are already saved in python for an specified reason to run...

Eg:

```
if  
else
```

```
for
while
return
print
```

5.Literals

→Literals are the datatypes that need to be stored in variables ...

Eg:

```
num =90
name ='praveen'
```

6.Operator

→ +, -, =

7.Statements

→Statements are the instructions given to the program...

Eg:

```
num=90
age =2
if age >=18:
print(age)
```

What is comments?

→ Once comments are open the lines inside will never execute in python file..

2 types of comments

1.single line comment(#)

It is used to comment only one line

Eg:

```
age =2
if age >=18: # this check age is greater or equal
print(age)
```

2.multi-line comment('' '' , "" "")

It is used to comment more than one line

Variables rules:

1.Bad ways

>can't use number at 1st position

>can't use special char anywhere

>can't use space

>can't use keywords

Eg:

2num =90

\$num =88

n um =98

if = 67

2.Good ways

>small letters and cap letters, (_) underscore

Eg:

num =1

nUm_2=99

SBI_teja_details ={'name': ' teja', 'ac_num' : '12345678900'}

ICIC_garikapti_details ={'name': 'teja', 'ac_num ': '12345678900'}

ass

num =90

print(num)

num_3, num_2 =56,60

print(num_3)

```
print(num_2)
```

Swapping of two variables

```
a, b = 45, 67
```

```
print('a=', a)
```

```
print('b=', b)
```

```
a, b = b, a
```

```
print('a=', a)
```

```
print('b=', b)
```
